## **Appendix F**

## **Selected Solutions**

## F.9 Chapter 9 Solutions

- 9.1 The most important advantage of doing I/O through a trap routine is the fact that it is not necessary for the programmer to know the gory low-level details of the specific hardware's input/output mechanism. These details include:
  - the hardware data registers for the input and output devices
  - the hardware status registers for the input and output devices
  - the asynchronous nature of the input relative to the executing program

Besides, these details may change from computer to computer. The programmer would have to know these details for the computer she's working on in order to be able to do input/output. Using a trap routine requires no hardware-specific knowledge on part of the programmer and saves time.

- 9.3 (a) Some external mechanism is the only way to start the clock (hence, the computer) after it is halted. The Halt service routine can never return after bit 15 of the machine control register is cleared because the clock has stopped, which means that instruction processing has stopped.
  - (b) STI R0, MCR This instruction clears the most significant bit of the machine control register, stopping the clock.
  - (c) LD R1, SaveR1
  - (d) The RET of the HALT routine will bring program control back to the program that executed the HALT instruction. The PC will point to the address following the HALT instruction.
- 9.5 Note: This problem should be corrected to read as follows:

.ORIG x3000 LEA RO, LABEL

```
STR R1, R0, #3
TRAP x22
TRAP x25
LABEL .STRINGZ "FUNKY"
LABEL2 .STRINGZ "HELLO WORLD"
.END
```

Answer: FUN

9.7 Note: This problem belongs in chapter 10.

The three errors that arose in the first student's program are:

- 1. The stack is left unbalanced.
- 2. The privilege mode and condition codes are not restored.
- 3. Since the value in R7 is used for the return address instead of the value that was saved on the stack, the program will most likely not return to the correct place.

- 9.11 The label S\_CHAR cannot be represented in 9-bit signed PC offset for the ST R0, S\_CHAR and LEA R6, S\_CHAR instructions. The range for a PCoffset9 instruction (such as LEA or ST) is only from -256 to 255 locations. Due to the number of locations that have been set aside for BUFFER, the location labeled S\_CHAR falls oustide of this range for the ST and LEA instructions. This problem can be fixed by switching the lines BUFFER .BLKW 1001 and S\_CHAR .FILL x0000.
- 9.13 The linkage for JSR A is destroyed when JSR B is executed.
